

Ideation Phase

Brainstorm & Idea Prioritization

Date	19 September 2026
Team ID	Shaik Irshad - 238W1A4256
Project Name	Automated Network Request Management In ServiceNow
Maximum Marks	4 Marks

Brainstorming provided an open space for the team to generate ideas for solving the network-request problem before committing to a build. Ideas were listed without judgment, then grouped by theme, and finally prioritized on importance versus feasibility to decide what would actually be implemented in this project versus what would be left as a future enhancement.

Step 1 — Team Gathering & Problem Statement

The team agreed on a single guiding question to focus the brainstorming session, framed as a “How Might We” statement:

PROBLEM

How might we automate and standardize the network service request process so employees get a consistent request form, automatic validation, and clear visibility into approval status?

Step 2 — Brainstorm, Idea Listing & Grouping

Ideas raised during the session were written down individually and then clustered into four related themes that map directly onto the ServiceNow building blocks used later in the project: the request form and UI, the backend data model, the automation and approval mechanism, and notification/tracking.

Step 2 — Brainstormed Ideas Grouped by Theme

Request Form & UI	User & Backend Data	Automation & Approval	Notification & Tracking
Standardized Network Request catalog item	Auto-populate requester info (email, name, phone)	Flow Designer instead of custom scripting	Automatic email on request creation
Mandatory-field validation	Custom backend table for requests	Service Catalog trigger on submission	Approval related list on request record
Dynamic show/hide of Existing ID field	Auto-generated request / database number	Built-In Ask for Approval action	Flow execution logs for troubleshooting
Choice fields for connection & payment type	Approval Status field on backend record	Approved / Rejected conditional branch	End-to-end status traceability

Step 3 — Idea Prioritization

Each grouped idea was then placed on an Importance vs. Feasibility grid. Ideas that were both important and feasible within the project timeline (green) were carried into the actual ServiceNow implementation. Ideas that were important but not feasible to build in this project — mainly deeper integrations — were parked as future enhancements (orange). A few low-priority ideas (grey) were consciously left out of scope.

Outcome of Prioritization

The prioritization exercise directly shaped the final scope of the project:

- Implemented now: standardized catalog item and variables, mandatory-field validation, variable-set auto-population, custom backend table, Flow Designer automation, email notification, and the Ask for Approval / status-update logic.
- Deferred as future enhancements: Cisco DNA Centre / Ansible auto-provisioning, multi-level (manager + security) approval, Integration Hub connections, and Power BI / Tableau reporting dashboards.
- Left out of scope: a custom Service Portal widget, an expanded custom ACL framework, and a separate MERN/React application — the project instead relies on the standard Service Portal, default ServiceNow ACLs, and the ServiceNow platform itself.
