

Project Design Phase

Proposed Solution

Date	19 September 2026
Team ID	Shaik Irshad - 238W1A4256
Project Name	Automated Network Request Management In ServiceNow
Maximum Marks	2 Marks

S.No.	Parameter	Description
1	Problem Statement (Problem to be solved)	Employees who need network-related services face a fragmented, largely manual request process: information has to be collected inconsistently across channels, approvals are coordinated separately (e.g. over email/chat), and there is poor visibility into where a request stands — leading to manual data entry, delayed notifications, and difficulty tracking request status end to end.
2	Idea / Solution Description	• A ServiceNow Service Portal-based “Network Request” catalog item captures a standardized set of request details (connection type, existing ID where applicable, payment mode, address, requester info) with mandatory-field validation and dynamic field visibility (Catalog UI Policy). • A User Information variable set auto-populates the requester's email, name and phone number once “Opened on behalf of” is selected — no re-typing of known details. • A Flow Designer flow (triggered on submission) creates a record in a custom backend table with an auto-generated request number, sends an email notification, raises an approval request (Ask for Approval), and updates the record's Approval Status to Approved or Rejected based on the outcome. • An Approval Request relationship exposes the linked approval record directly on the request form, giving the requester and admins end-to-end traceability from submission to final status — all without any custom scripting.
3	Novelty / Uniqueness	• The uniqueness here isn't a new algorithm — it's a fully configuration-first, low-code build: the entire request-to-approval lifecycle (validation, auto-population, record creation, notification, approval, status update) is delivered using only native ServiceNow capabilities (Catalog UI Policy, Variable Set auto-population, Flow Designer, and the built-in Approval Engine), with no custom Script Includes or Business Rules. • This keeps the solution easy to maintain, quick to extend to other IT services, and closely aligned with ServiceNow's own recommended low-code practices, while still achieving full traceability of every request.
4	Social Impact / Customer Satisfaction	• Removes repetitive manual data entry for employees raising network requests, reducing effort and the chance of inconsistent or incomplete information. • Gives requesters clear, automatic confirmation (email + request number) that their submission went through, reducing uncertainty and follow-up queries to IT. • Provides visibility into approval progress through the Approval Related List, replacing informal status-chasing with a single source of truth. • Speeds up the overall turnaround from request to resolution by removing manual coordination steps between the requester, IT and the approver.

S.No.	Parameter	Description
5	Business Model (Revenue Model)	• This is an internal IT-service-efficiency solution rather than a customer-facing commercial product, so the primary value is cost avoidance and productivity gain: fewer IT support hours spent on manual intake and status queries, fewer errors from inconsistent request data, and faster fulfilment of network requests across the organization. • As a scoped ServiceNow application built entirely with configuration, the same request-and-approval pattern could additionally be packaged as a reusable accelerator/template and offered to other teams or client organizations already running ServiceNow — though that packaging is a possible future direction and was not part of this project's delivered scope.
6	Scalability of the Solution	• Runs natively on ServiceNow's multi-instance cloud (Now Platform), so it inherits the platform's built-in scalability, availability and security without any custom infrastructure work by the project team. • As a scoped application, the same catalog item + variable set + UI Policy + Flow Designer + Approval Engine pattern can be extended to other IT service requests — device provisioning, access requests, or other infrastructure requests — by cloning and adapting the existing components rather than rebuilding from scratch.
